(54) Title: A METHOD FOR COMMUNICAION NETWORK PERFORMANCE ANALYSIS

(57) Abstract: The present invention relates to a method for communication network parameter setting comprising the steps of a) acquiring and storing information related to a1) service requests issued by terminals attached to said network, a2) positions of said terminals, and a3) establishment of the requested service for said terminals, b) matching, based on the position information, said information to a grid of unit areas, the grid of unit areas representing a geographical region in which said network is operated, c) processing said information per unit area, d) outputting said processed information and e) modifying communication network operating parameters based on said outputted processed information.

TITLE OF THE INVENTION

A METHOD FOR COMMUNICATION NETWORK PERFORMANCE ANALYSIS

5

FIELD OF THE INVENTION

The present invention relates to a method for communication
10 network performance analysis.

BACKGROUND OF THE INVENTION

15 Recently, communication networks have widely spread and are
used by a continuously increasing number of subscribers. In
order to cope with the increasing number of subscribers and
correspondingly the increasing number of terminals of said
subscribers which are potentially attached to the network for
20 communication purposes, communication networks have to be
most carefully planned in order that the network can be
operated smoothly while meeting all requirements of the
subscribers.

25 It is to be noted that the present invention is not limited
to a specific type of communication network. It may be for
example a wireless communication network such as the UMTS
network or any other communication network. Also, network
planning is to be understood as a process of setting network
30 operating parameters such as transmit power, antenna
characteristics, selection of transmitter sites and/or
decision to install further transmitter sites. (A transmitter
site in the example of a UMTS network means a Node_B
(corresponding to a base station BS in GSM)). In order to
35 effectively perform such a network planning, however, a most
properly executed network performance analysis is required,

since otherwise network planning would result in a mere „trial and error“ process which is cumbersome and rather time consuming, and the success of which is doubtful and can not be verified quantitatively.

5

The requirements of the users to be met by the communication network can be deemed to be represented by the services the subscribers have subscribed to and among which they may select for communication purposes.

10

The definition of the term „service“ as used herein is to be understood in its broadest sense and can, for example, be a PDP (Packet Data Protocol) context, while if the end user service (the actual application run on the terminal such as e.g. TCP/IP (Transmission Control Protocol/ Internet Protocol) or voice call, SMS (Short Message Service), video conferencing) is known, also that can be used as definition of the service. More generally, a service is characterized by at least one service attribute, which is for example bit rate, BLER (service performance target) and Eb/No (energy per bit over noise) or a combination of these and/or others known in the field of communication networks. The main issue is that the definition of service is related to a set of at least one attribute and these attributes define the dimensions of the „information matrix“ to be used. The mobile network has for example the following attributes concerning the „service“: The service performance target (BLER), Eb/No target, and/or the used bit rate. Also, the definition of service can be dependent on performance management (PM). PM is defining with what abstraction the service can be detected (UMTS traffic class (real-time, interactive, streaming, background) vs. the actual service (e.g. different real-time services distinguishable by used bit-rate) etc.)

35 Setting of network operating parameters in a way so as to improve and/or optimize the network performance requires a

knowledge of the „behavior“ of the network, in particular in downlink direction (from the transmitter stations to the terminals).

5 Traditionally the downlink direction information for optimization purposes has been very difficult to acquire. The only way to collect coverage related data has been with drive tests with field tool and this requires relatively lot manpower which makes data collection quite expensive and also
10 time consuming. Furthermore, the field tool data has not been transferred to Network Management System (NMS) for further analysis and thus the coverage information is based either on planning tool (very inaccurate) or statistical „snapshots“ based on drive tests in the network (these are in addition
15 only related to a limited area of the network dependent on the number of drive tests conducted simultaneously).

SUMMARY OF THE INVENTION

20

Consequently, it is an object of the present invention to provide an improved method for communication network performance analysis.

25 According to the present invention, the above object is for example achieved by a method for communication network performance analysis comprising the steps of

- a) acquiring and storing information related to
 - a1) service requests issued by terminals attached
30 to said network,
 - a2) positions of said requesting terminals, and
 - a3) establishment of the requested service for said terminals,
- b) matching, based on the position information, said
35 information to a grid of unit areas, the grid of unit

areas representing a geographical region in which said network is operated,

- c) processing said information per unit area,
- d) outputting said processed information.

5

According to favorable further developments

- the method comprises a step of modifying communication network operating parameters based on said outputted processed information,

10

- said information related to the establishment of the service comprises at least a success indication indicating that said service was successfully established or not and at least one service attribute;

15

- said processing comprises a step of logically combining said service request information and said success information;

- said processing comprises a further step of summing said at least one service attribute parameter;

20

- said processing comprises the further steps of sorting said stored information according to said at least one service attribute, thereby obtaining a plurality of information sets, each being representative of an individual service distinguishable by said at least one service attribute, and

25

- selecting one of said information sets according to the service attribute for being output;

- said acquired information is stored for a predetermined time;

30

- said processing comprises a step of filtering said stored information using a selectable time window.

- said summed at least one service attribute parameter is divided by the time period defined by said selected time window.

35

By virtue of the present invention, which includes the terminal position information to a certain event/measurement as additional information for the network optimization process,

5 basically the following advantages can be achieved:

- network planning can be achieved at lower costs since drive tests can be dispensed with,

- service coverage information is collected in an automatic manner and in a centralized manner at for example in the

10 network management system NMS, (once collected, it may, however, be transferred and/or distributed to other entities)

- permanently tracing a terminal is no longer required (while still possible), so that less information is to be collected and managed, as only the service request location and

15 information on the success of the request is collected together with at least one service attribute,

- the proposed method is applicable to any mobile/cellular communication network utilizing positioning methods.

20 Thus, with this invention it is possible to create service maps (a grid of unit areas) by utilizing advanced positioning methods to collect service „coverage area“ data from the network for optimization purposes. These maps can be used as visual input for the operator when comparing the intended and
25 real network performance. Hence, modifying communication network operating parameters based on said outputted processed information as represented in the created maps is enabled.

30 Thus, stated in other words, according to the present invention it is conceived to combine the terminal service request and position information and collect this data in a centralized manner. As a result a statistical coverage map can be generated and output, i.e. a geographical map showing
35 areas where a certain service has been successfully provided. Another issue is to utilize the same data but take another

projection of it and display (e.g. busy hour) throughput statistics on a map. The resolution of this map is the same as the accuracy of the positioning method, which has a higher resolution than the cell resolution. Thus, as an additional benefit of this invention, the traditional cell coverage area based analysis and visualization can be dispensed with. The resolution of the information matrix depends on the resolution of the used location information. Current networks provide at least cell-id information. This performance is increased by the present invention by utilizing more advanced location based services (LCS) positioning methods.

The modifying step is mostly performed in an iterative manner and can be implemented automatically or involve the interaction of an operator.

BRIEF DESCRIPTION OF THE DRAWINGS

In the following, the present invention will be described in greater detail with reference to the accompanying drawings, in which

Fig. 1 shows an example of a grid of unit areas, the grid of unit areas representing a geographical region in which said network is operated, with information related to at least one service attribute parameter processed per unit area being outputted;

Fig. 2 shows an example of a grid of unit areas, the grid of unit areas representing a geographical region in which said network is operated, with information related to at least one service processed per unit area being outputted;

Fig. 3 shows a block circuit representation of entities involved in the present method and some signaling there

between in connection with an embodiment of the present invention;

Fig. 4 shows an illustration of several layers of
5 information, each layer representing a service, the services being distinguishable by means of a service attribute;

Fig. 5 shows an illustration for explaining logically combining said service request information and said success
10 information; and

Fig. 6 shows a block circuit representation of entities involved in the present method and some signaling there between in connection with another embodiment of the present
15 invention.

DETAILED DESCRIPTION OF THE EMBODIMENTS

20 Now, the present invention will be described with reference to the attached drawings.

Fig. 3 shows a block circuit representation of entities involved in carrying out the present method and some
25 signaling there between in connection with an embodiment of the present invention. As shown in Fig. 3, when implementing the present invention there are involved the mobile network including all network entities, applications run on and/or by means of the mobile network such as live icehockey
30 transmissions, yellow pages or email. For illustration purposes a position estimation and information machine (e.g. a mobile location center such as a GMLC (Gateway Mobile Location Center) or SMLC (Serving Mobile Location Center)) and a network management or corresponding system entity
35 denoted as NMS are shown separately, even though they may be considered as forming part of the mobile network as such.

Between these entities, requests and resulting information can be transmitted via interfaces. A position estimation request to the position estimation and information machine
5 can be initiated either by the mobile network (i.e. a control entity thereof), the network management system NMS, the application or the terminal (User Equipment UE). In response to such a request, the position estimation and location machine retrieves the position estimate of individual
10 terminals. The position information is associated to services requested for and/or used by the terminals. Hence, as a result, information related to service requests issued by terminals attached to said network, positions of said requesting terminals, and establishment of the requested
15 service for said terminals is acquired and stored in the network management system NMS.

The mobile network reports to the network management system information related to the establishment of the service which
20 comprises at least a success indication indicating that said service was successfully established or not and at least one service attribute. This indication is provided for each terminal, i.e. per subscriber attached to the network.

25 Based on the service attribute, indexing of the service can be accomplished. This means that for each service a separate set of information is maintained and that each set of information is selectable for being processed/displayed based on the at least one service attribute. More precisely, for a
30 terminal issuing a service request it is acquired and stored that the terminal issued a request, whether the request was successful or not, to which service the request belonged and the position information of the terminal.

35 This is illustrated in Fig. 4. Fig. 4 shows an illustration of several layers of information, each layer representing a

service, the services being distinguishable by means of a service attribute. As mentioned before, the mobile network provides an indexing for a service in the information matrix. Thus, information related to services A, B, C, X are stored
5 and the position machine fills the service position information upon request (of the respective service by a terminal). For example, service A, B, C, X are characterized by the service attribute bitrate, and the service attribute parameter is the individual bitrate such as 16 kbit/s, 32
10 kbit/s, 64 kbit/s or 128 kbit/s, whether this bitrate is the user bitrate, or including some overhead is not relevant for the method. Here, filling means that there is performed a matching, based on the position information, of said information to a grid of unit areas, the grid of unit areas
15 representing a geographical region in which said network is operated. Stated in other words, the information is mapped to e.g. an x-y-coordinate system. A minimum resolution of the coordinate system could e.g. be 10*10 m and be graphically represented as a single pixel (display picture element).
20 Other resolutions are nevertheless also possible.

Thus, said stored information is sorted according to said at least one service attribute, thereby obtaining a plurality of information sets, each being representative of an individual
25 service distinguishable by said at least one service attribute, and one of said information sets is selectable according to the service attribute for being output. Of course, more than one sets can be selected for being output simultaneously.

30

However, it is also possible to generate a map based solely on the information related to the location services: what service is active in which area of e.g. the city. In this connection, it has to be noted that the information related
35 to the establishment of the service comprises at least a success indication indicating that said service was

successfully established or not and at least one service attribute (for identifying the service).

The processing comprises a step of logically combining said
5 service request information and said success information as illustrated in Fig. 5. An area concerned is represented by a „cloud“. The cloud on the right represents the entire area in which terminals issued a service request for a specific service such as service A. The cloud on the left represents
10 the same geographical entire area, however only in a part of that area the service requests were successful so that the service could be established at all (optionally weighted/multiplied by established quality of service QoS such as the established bit-rate or the like). The resultant
15 coverage area is represented in the lower cloud by the gray shaded portion.

Apparently, in the illustrated example, the logically combining corresponds to a logical AND. Nevertheless, any other (logical) combining can be performed such as NAND,
20 which then results in the complementary area indicating the area in which the requested service could not be established.

Note that when the features according to the present invention are activated, the service request is „marking“
25 (or preparing) service layer in the information matrix, the position is requested from the „positioning estimation machine“, and position information is filled to the „information layer“ marked before. A „cloud“ (right hand one) in Fig. 5 corresponds thus to one of the layers for
30 respective services shown in Fig. 4. Additionally there is another information matrix (cloud on the left in Fig. 5) related to the service success, this is filled in similar manner as before (filled with 0 and 1). Also, it is possible to generate one or more other weight layers related to
35 service performance (or QoS) and use that weighting also when determining the service coverage plot. A weight layer may

also be referred as service success map, and a weight layer may be established per service attribute. (It is further to be noted that instead of a service success map, the complementary information, i.e. a service failure map can be established and used, as the service failure is also to be regarded as information related to the establishment of the requested service for said terminals and the service success map includes an indication whether the service was successful or not.) For example, services may be identified as successfully established real-time services, and among these, weighting according to e.g. the bit-rate can be performed, which means that a real-time service of a specific bit-rate is selected.

After these (at least) two matrices are filled, the UE identification (IMSI etc.) can be released. This results in the map representation being established anonymously without identification of individual terminals.

Furthermore, since the evaluation is based on a limited / discrete number of data corresponding to the number of terminals requesting and/or using a service, the grid of unit areas is not continuously filled but filled with discrete data only. Therefore, in order to improve graphical representation when outputting the processed data, interpolation and/or extrapolation or other techniques such as those relying e.g. on neural networks can optionally be used in order to conclude data for „missing“ pixels (unit areas of the grid). Outputting processed data can be performed as a map per individual service or cumulative for all services together in the same representation, or for a specific service attribute of a service (for an individual service or for several services cumulative provided that these services have the same service attribute) or the like.

It is however to be noted that even though outputting has been referred to herein above as outputting in a map

representation, outputting can be performed visually or acoustically, and if visually, as a representation of a map or as bar diagrams or the like.

5 Fig. 2 shows an example of a grid of unit areas, the grid of unit areas representing a geographical region in which said network is operated, with information related to at least one service processed per unit area being outputted. This figure represents the result of a processing which comprises the
10 further steps of sorting said stored information according to said at least one service attribute, thereby obtaining a plurality of information sets, each being representative of an individual service distinguishable by said at least one service attribute, and selecting one of said information sets
15 according to the service attribute for being output. Namely, as shown in Fig. 2, there are different services distinguished by the bit-rate as a service attribute and additionally the speed of the terminal. Here, the services are displayed simultaneously in the x-y coordinate system,
20 each services provisioned in a respective area being represented in a different shade of gray. Color representation is of course also possible. Nevertheless, a corresponding map can be established also with only a single service area being displayed.

25 Stated in other words, Fig. 2 represents a service coverage map. In order to be able to provide such a service coverage map, according to the present invention the following measures are initiated, as has been described above:

30 1. Acquire and store the service request information and related position information (derived by position estimation machine e.g. GMLC, SMLC & related middleware et al). The storing is done for e.g. a predetermined period of time. The length of the period depends on the purpose of the analysis,
35 that is, one month storage period is sufficient if the analysis is conducted for periods up to one month or shorter

periods. Store in similar manner information about requests, which were successfully completed (service success map).

2. Process the stored information so that the information is per pixel and per service basis (e.g. 10m x10m map area, typically digital maps in planning tool/NMS consists of pixels). Stated in other words, perform a matching, based on the position information, of said information to a grid of unit areas, the grid of unit areas representing a geographical region in which said network is operated.

3. As an option, choose a time filter for the coverage map (e.g. time of the day, rush hour, weekends, last two weeks, or the like) to select data for one output plot/display by filtering the data with the time filter.

4. Weight (multiply) the service request map(s) with the service success map(s), i.e. perform a logical combining of these information.

5. Optionally, interpolate/extrapolate/use advanced methods like neural networks to conclude the data for missing pixels, or just leave empty pixels blank.

6. Plot service coverage map(s) or output the processed information otherwise, e.g. on a display device connected to the network management system NMS or corresponding system. This outputting can be performed per individual service or „cumulative“ for all services on the same plot.

Individual services can be selected based on at least one service attribute such as bit-rate and/or delay requirement or any other QoS parameter by means of which services can be distinguished.

Fig. 6 shows a block circuit representation of entities involved in the present method and some signaling there between in connection with another embodiment of the present invention. The block circuit representation is identical to Fig. 3, while instead of „per service“ data representation,

now the service attribute parameters are concerned. More precisely, according to this embodiment, throughput data are informed from the network to the network management system. It is however, to be noted that these data are also present
5 in the previous example, and can be extracted from the available data sets with a suitable processing. In the presently concerned embodiment, throughput data correspond to the bit-rate of the respective services, and the processing comprises summing the bit-rates of the individual services
10 established in a unit area of the grid.

Such a processing yields a map representation as shown in Fig. 1. Fig. 1 shows an example of a grid of unit areas, the grid of unit areas representing a geographical region in
15 which said network is operated, with information related to at least one service attribute parameter processed per unit area being outputted. That is, here, each unit area represents the summed bit-rate of the services requested and/or activated in the
20 unit area. The summed bit-rate thus provides throughput information in the area concerned and is indicative of an amount of data transfer at a given time period in a given area.

25 Stated in other words, Fig. 1 represents a throughput map. In order to be able to provide such a throughput map, according to the present invention the following measures are initiated, as has been described above:

1. Store the service request information, completion
30 (success) information and related position information (derived by position estimation machine e.g. GMLC, SMLC & related middleware et al), e.g. for predetermined period of time. The length of the period depends on the purpose of the analysis, as mentioned previously above.
- 35 2. Process the above information so that the information is per pixel basis (this time not per service) (e.g. as

mentioned previously, 10m x 10m map area, typically digital maps in planning tool/NMS consists of pixels), (including a logical combining of the information as mentioned above in connection with the coverage map)

5 3. Optionally, choose a time filter for the throughput map (e.g. time of the day, busy hour, weekend, last two weeks or the like) to select data for one output plot/display by filtering the data with the time filter.

10 4. For throughput estimation, sum the bit-rates of the services in the same pixel, i.e. per unit area of the grid. (This yields the integrated bit-rate value over the storage cycle.) Then, as an option, divide the sum with the time period defined by the time filter used for data processing. (This yields the average bit-rate during the time defined by
15 the time filter, i.e. in the time window thus defined.)

5. Optionally, interpolate/extrapolate/use advanced methods like neural networks to conclude the data for missing pixels, or just leave empty pixels blank.

20 6. Output throughput map(s) as a result of the processing. Fig. 1 shows several throughput maps simultaneously as throughput bit-rates of 16 kbit/s, 32 kbit/s, 64 kbit/s, 100 kbit/s, 200 kbit/s, and 400 kbit/s are simultaneously displayed which could also be displayed separately.

25

Herein before, the invention has been described with a focus on specific embodiments thereof. However, it has to be noted that It is also possibly to utilize also different steps to conclude e.g. the service coverage, and herein above only one
30 example has been given. Another possibility is to store the locations of successful „service releases“, as a service release information is also considered to represent information related to service requests. The benefit of these methods is that only the service request/release location is
35 collected and information on the success of the requested service.

Tracing a terminal (mobile station) which uses a specific service X is another possibility. This method is requiring more data to be collected. Tracing means continuous
5 monitoring and following the terminal through the network.

All the proposed methods can also combined and utilize the combination information when determining e.g. the service coverage map.

10

In addition to the „success layer“ it is possible to utilize a QoS (service performance) layer when determining the resultant service coverage plot. Naturally for this the QoS information must be collected.

15

A benefit of time filter resides in that it is possible to compare the service coverage in busy hours versus „quiet“ times. This demonstrates the effect of cell breathing. Furthermore: operators (or virtual operators), apart from
20 their technical network planning and optimization efforts, can use this information in their business planning: for example, with pricing the coverage maps can be tailored.

Location information is a new dimension for the optimization
25 process. The current cell based thinking is more a limitation than benefit. If the terminal location information can be effectively utilized, the optimization can concentrate on geographical locations and prioritizing those rather than prioritizing of cells. Also, the accuracy of the pure cell
30 identifier is not sufficient to collect the described information. Therefore advanced positioning methods should be applied. Those methods could be enhanced cell-based methods (e.g. TA (Timing Advance), RTT (Round Trip Time), Rx-level (Rx: Reception)), TOA (Time Of Arrival), AOA (Angle of
35 Arrival), any kind of observed time difference (e.g. E-OTD (Enhanced Observed Time Difference), OTDOA (Observed Time

Difference Of Arrival); IPDL (Idle Period Downlink)-OTDOA) and GPS (Global Positioning System) (e.g. A-GPS (Assisted GPS); stand-alone GPS) or any combination of those.

5 There are several scenarios where the service request and the position of the user can be collected. Those scenarios can be divided into two main categories: one time interrogation (e.g. at the beginning of the service request, at the end or during the service usage), and continuous interrogation (e.g. during the service is used - also referred to as service tracing).

The one-time interrogation has the advantage that it might reflect the real situation quite well and it does not cause too much load to the network. Instead, the continuous
15 interrogation has the advantage of reflecting the dynamics of a real situation much better than the more one-time pseudo-dynamic case. The network must be dimensioned accordingly or off-peak free capacity could be utilized to collect this data.

20 It has to be noted that the particular manner of collecting the location information e.g. by means of the GMLC or SMLC is out of the scope of the present invention and thus not described in detail. In this regard, the interested reader
25 should refer to other literature / patent applications dealing with that particular topic.

Accordingly, as has been described herein above, the present invention relates to a method for communication network
30 parameter setting comprising the steps of a) acquiring and storing information related to a1) service requests issued by terminals attached to said network, a2) positions of said requesting terminals, and a3) establishment of the requested service for said terminals, b) matching, based on the
35 position information, said information to a grid of unit areas, the grid of unit areas representing a geographical

region in which said network is operated, c) processing said information per unit area, d) outputting said processed information and e) modifying communication network operating parameters based on said outputted processed information.

5

While the invention has been described with reference to a preferred embodiment, the description is illustrative of the invention and is not to be construed as limiting the invention. Various modifications and applications may occur
10 to those skilled in the art without departing from the true spirit and scope of the invention as defined by the appended claims.

Claims

- 5 1. A method for communication network performance analysis comprising the steps of
- a) acquiring and storing information related to
 - 10 a1) service requests issued by terminals attached to said network,
 - a2) positions of said requesting terminals, and
 - a3) establishment of the requested service for said terminals,
 - b) matching, based on the position information, said information to a grid of unit areas, the grid of unit
 - 15 areas representing a geographical region in which said network is operated,
 - c) processing said information per unit area, and
 - d) outputting said processed information.
- 20 2. A method according to claim 1, further comprising the step of
- e) modifying communication network operating parameters based on said outputted processed information.
- 25 3. A method according to claim 1, wherein said information related to the establishment of the service comprises at least a success indication indicating that said service was successfully established or not and at least one service attribute.
- 30 4. A method according to claim 3, wherein said processing comprises a step of logically combining said service request information and said success information.
- 35 5. A method according to claim 4, wherein

said processing comprises a further step of summing said at least one service attribute parameter.

6. A method according to claim 4, wherein

5 said processing comprises the further steps of
 sorting said stored information according to said
 at least one service attribute, thereby obtaining a
 plurality of information sets, each being representative
 of an individual service distinguishable by said at
10 least one service attribute, and

 selecting one of said information sets according to
the service attribute for being output.

7. A method according to claim 1, 2, 3, 4, 5, or 6 wherein

15 said acquired information is stored for a predetermined
time.

8. A method according to claim 1, 2, 3, 4, 5, or 6 wherein

20 said processing comprises a step of filtering said
stored information using a selectable time window.

9. A method according to claim 8 when dependent on claim 5,
wherein said summed at least one service attribute parameter
is divided by the time period defined by said selected time
25 window.

C. DOCUMENTS CONSIDERED TO BE RELEVANT

Category *	Citation of document, with indication, where appropriate, of the relevant passages	Relevant to claim No.
E	US 6 442 393 B1 (HOGAN BILLY) 27 August 2002 (2002-08-27) column 3, line 60 -column 4, line 39	1-9
X	EP 0 431 956 A (MOTOROLA INC) 12 June 1991 (1991-06-12) the whole document	1-9
A	US 5 920 607 A (BERG MYRON) 6 July 1999 (1999-07-06) abstract	1-9
A	US 5 598 532 A (LIRON MOSHE) 28 January 1997 (1997-01-28) abstract	1-9
	--- -/--	

☒ Further documents are listed in the continuation of box C.

☒ Patent family members are listed in annex.

* Special categories of cited documents :

- "A" document defining the general state of the art which is not considered to be of particular relevance
- "E" earlier document but published on or after the International filing date
- "L" document which may throw doubts on priority claim(s) or which is cited to establish the publication date of another citation or other special reason (as specified)
- "O" document referring to an oral disclosure, use, exhibition or other means
- "P" document published prior to the International filing date but later than the priority date claimed

- "T" later document published after the international filing date or priority date and not in conflict with the application but cited to understand the principle or theory underlying the invention
- "X" document of particular relevance; the claimed invention cannot be considered novel or cannot be considered to involve an inventive step when the document is taken alone
- "Y" document of particular relevance; the claimed invention cannot be considered to involve an inventive step when the document is combined with one or more other such documents, such combination being obvious to a person skilled in the art.
- "&" document member of the same patent family

Date of the actual completion of the international search

7 February 2003

Date of mailing of the international search report

24.02.2003

Name and mailing address of the ISA

European Patent Office, P.B. 5818 Patentlaan 2
NL - 2280 HV Rijswijk
